(54) **A developing cartridge**

(57) A developing cartridge for developing a latent image formed on the photosensitive member, wherein the developing cartridge is detachably mountable to a main assembly of an electrophotographic image forming apparatus, the developing cartridge includes a cartridge frame; developing means for developing, with toner, the latent image formed on the photosensitive member of the main assembly of the apparatus, when mounted to the main assembly of the electrophotographic image forming apparatus; a first projected portion outwardly projected from the cartridge frame portion adjacent one longitudinal end of the developing means, wherein the first projected portion is supported by a first supporting member provided in the main assembly of the apparatus when the cartridge is mounted to the main assembly; a second projected portion outwardly projected from the cartridge frame portion adjacent the other longitudinal end of the developing means, wherein the second projected portion is supported by a second supporting member provided in the main assembly of the apparatus when the cartridge is mounted to the main assembly; a first urging force receptor portion outwardly projected from the cartridge frame portion adjacent one longitudinal end of the developing means, wherein the first urging force receptor portion receives urging force by a first elastic member provided in the main assembly when the cartridge is mounted to the main assembly; a second urging force receptor portion outwardly projected from the cartridge frame portion adjacent the other longitudinal end of the developing means, wherein the second urging force receptor portion receives urging force by a

second elastic member provided in the main assembly when the cartridge is mounted to the main assembly; a first contact portion outwardly projected from the cartridge frame portion adjacent one longitudinal end of the developing means, wherein the first contact portion contacts a first fixed portion provided in the main assembly when the cartridge is mounted to the main assembly; a second contact portion outwardly projected from the cartridge frame portion adjacent one longitudinal end of the developing means, wherein the second contact portion contacts a second fixed portion provided in the main assembly when the cartridge is mounted to the main assembly.

FIG. 22

FIG. 24

FIELD OF THE INVENTION AND RELATED ART

The present invention relates to a developing cartridge for developing a latent image formed on an electrophotographic photosensitive member when an image is formed on a recording material through an electrophotographic process, and an electrophotographic image forming apparatus using the developing cartridge.

Heretofore, the following structure is known as multi-color image forming apparatus for forming a multi-color image on a recording material through an electrophotographic process. A plurality of developing devices accommodating different color developers which are arranged on a rotation selection mechanism, are disposed around an electrophotographic photosensitive drum. A developing device accommodating a color developer is brought to be faced to the photosensitive drum to develop a latent image thereon. The developed image is transferred onto the recording material. The developing and transferring operations are carried out for respective colors, so that multi-color image is formed. The developing device is in the form of a cartridge which is detachably mountable to the main assembly of the image forming apparatus to facilitate the maintenance operation of the users.

Generally, the structure for inserting the developing device into the main assembly of the apparatus is such that developing device is inserted in the longitudinal direction of the developing roller from a predetermined position, in order to reduce the area of the opening of the main assembly.

The present invention is intended to further improve such a developing device.

SUMMARY OF THE INVENTION

Accordingly, a principal object of the present invention is to provide a developing cartridge having an improved operability and an image forming apparatus to which the developing cartridge is detachably mountable.

It is another object of the present invention to provide a developing cartridge which can be correctly positioned in a main assembly of an image forming apparatus, and to provide an image forming apparatus to which the developing cartridge is detachably mountable.

It is a further object of the present invention to provide a developing cartridge which is provided with a positioning member for positioning the cartridge in the main assembly of an image forming apparatus, and to provide an image forming apparatus to which the developing cartridge is detachably mountable.

It is a further object of the present invention to provide a developing cartridge having an outward projection to be supported by a supporting portion in a main

assembly of an image forming apparatus, and to provide an image forming apparatus to which the developing cartridge is detachably mountable.

5 It is a further object of the present invention to provide a developign cartridge having an outward projection for receiving urging force from an elastic member in a main assembly of an image forming apparatus, and to provide an image forming apparatus to which the developing cartridge is detachably mountable.

10 According to an aspect of the present invention, there is provided a developing cartridge for developing a latent image formed on the photosensitive member, wherein the developing cartridge is detachably mountable to a main assembly of an electrophotographic image forming apparatus, the developing cartridge comprising: a cartridge frame; developing means for developing, with toner, the latent image formed on the photosensitive member of the main assembly of the apparatus, when mounted to the main assembly of the electrophotographic image forming apparatus; a first projected portion outwardly projected from the cartridge frame portion adjacent one longitudinal end of the developing means, wherein the first projected portion is supported by a first supporting member provided in the main assembly of the apparatus when the cartridge is mounted to the main assembly; a second projected portion outwardly projected from the cartridge frame portion adjacent the other longitudinal end of the developing means, wherein the second projected portion is supported by a second supporting member provided in the main assembly of the apparatus when the cartridge is mounted to the main assembly; a first urging force receptor portion outwardly projected from the cartridge frame portion adjacent one longitudinal end of the developing means, wherein the first urging force receptor portion receives urging force by a first elastic member provided in the main assembly when the cartridge is mounted to the main assembly; a second urging force receptor portion outwardly projected from the cartridge frame portion adjacent the other longitudinal end of the developing means, wherein the second urging force receptor portion receives urging force by a second elastic member provided in the main assembly when the cartridge is mounted to the main assembly; a first contact portion outwardly projected from the cartridge frame portion adjacent one longitudinal end of the developing means, wherein the first contact portion contacts a first fixed portion provided in the main assembly when the cartridge is mounted to the main assembly; a second contact portion outwardly projected from the cartridge frame portion adjacent one longitudinal end of the developing means, wherein the second contact portion contacts a second fixed portion provided in the main assembly when the cartridge is mounted to the main ass mbly.

55 These and other objects, features and advantages of the present invention will become more apparent upon a consideration of the following description of the preferred embodiments of the present invention taken in

conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

DESCRIPTION OF THE PREFERRED EMBODIMENTS

A developing cartridge and an electrophotographic image forming apparatus according to embodiments of the present invention will be described.

(First Embodiment)

Referring to Figures 1 to 12, the first embodiment of the present invention will be described. Figures 1 to Figure 3 illustrate an electrophotographic image forming apparatus; Figures 4 to 5 are perspective view of a developing cartridge; Figures 6 to Figure 10 are a mounting structure of the developing cartridge; and Figures 11 and 12, illustrate a drive transmission structure.

First, the description will be made as to a general arrangement of the electrophotographic image forming apparatus, and then as to the structure of the developing cartridge.

(Electrophotographic Image Forming Apparatus)

The general arrangement of the electrophotographic image forming apparatus of this embodiment will be described. Figure 1 is a side view of a laser beam printer as an exemplary image forming apparatus for forming a color image through an electrophotographic process. Charging means 2 uniformly charges a surface of an electrophotographic photosensitive member in the form of a drum (photosensitive drum) 1 which rotates at a constant speed. A laser beam corresponding to image information is projected through exposure means 3 onto the photosensitive drum 1 to form latent images thereon, which are developed by developing device Dy, Dm, Dc or Db. The developed images formed on the photosensitive drum 1 are superimposedly transferred sequentially onto an intermediary transfer member 4 so that color image is formed. The color image is transferred by transferring means 6 onto a recording material P, such as recording paper, OHP sheet or the like fed by feeding means 5 from a sheet feeding portion. The recording material P is fed to fixing means 7, where the color image is fixed. The recording material P is then discharged

to a discharging portion 8 at an upper surface of the device.

The structures of the respective portions will be described.

The photosensitive drum 1 is integrally mounted to a frame of cleaning means 9 for removing developer (toner) remaining on the photosensitive drum 1 after transfer of the toner image onto the recording material P, thus constituting a process cartridge (drum unit) U. The process cartridge U is demountably mounted to the main assembly of the image forming apparatus, and is exchanged by a user by himself when the lifetime of the photosensitive drum 1 ends.

The photosensitive drum 1 comprises an aluminum cylinder having a diameter of approx. 50 mm, and an organic photoconductive layer thereon, and is rotatably supported on a frame 9a of the cleaning means 9, which frame also functions as a holder for the photosensitive drum 1. Around the photosensitive drum 1, there are provided a cleaning blade 9b for scraping and removing the toner remaining on the photosensitive drum 1, and charging means 2. In this example, the photosensitive drum 1, cleaning means 9 and the charging means 2 are unified into a process cartridge U detachably mountable to the main assembly of the apparatus.

The photosensitive drum 1 receives driving force from an unshown driving motor to rotate in the counter-clockwise direction in Figure 1 in accordance with image forming operation.

The charging means 2 in this example is of contact charging type, and comprises a rotatable electroconductive roller in contact with the surface of the photosensitive drum 1, which roller is supplied with a voltage to uniformly electroconductive roller the surface of the photosensitive drum 1.

In the exposure means 3 for exposing the charged photosensitive drum 1, an image signal is supplied to an unshown laser diode, in response to which the laser diode projects the image light corresponding to the image signal onto the polygonal mirror 3a. The polygonal mirror 3a is rotated at a high speed by a scanner motor 3b, and the image light reflected by the mirror 3a is projected onto the photosensitive drum 1 rotating at a constant speed through an imaging lens 3c and a reflection mirror 3d, so that surface of the photosensitive drum 1 is imagewise exposed to the light, thus forming an electrostatic latent image.

The latent image is developed for each color by the latent image developing cartridge (developing device). The structure of the developing cartridge will be described, hereinafter.

The toner image developed by the developing cartridge is transferred onto the intermediary transfer member 4. Onto the intermediary transfer member 4, four color toner images on the drum are sequentially and superimposedly transferred. Therefore, the intermediary transfer member 4 is rotated clockwise in Figure 1 in synchronism with the outer peripheral speed of the pho-

tosensitive drum 1. The intermediary transfer member 4 having the toner images is passed to sandwich the recording material P with a transfer roller 6 as transferring means supplied with a voltage, by which the toner images are simultaneously transferred from the intermediary transfer member 4 onto the recording material P.

The intermediary transfer member 4 in this example comprises an aluminum cylinder having an outer diameter of approx. 150 mm, and an elastic layer of a material such as an intermediate resistance sponge, an intermediate resistance rubber or the like thereon. It is rotated by a gear fixed thereto.

After the toner image is transferred onto the intermediary transfer member 4, a small amount of toner remains on the surface of the photosensitive drum 1, and is removed by cleaning means 9. The cleaning means 9 has a cleaning blade 9b which is contacted to the drum surface and which scrapes the toner off the drum surface. The scraped toner is accumulated in a toner container 9c. The capacity of the container 9c is such that it is not filled with the removed toner accumulated before the lifetime of the photosensitive drum 1 ends. The removed toner in the container 9c is taken out by exchange of the drum unit U when the life of the photosensitive drum 1 ends.

The transferring means for transferring the toner images from the intermediary transfer member 4 onto the recording material P, is in the form of a transfer roller 6 in this example, and the roller 6 comprises a metal shaft, and an intermediate resistance foamed-elastic-member thereon, and is vertically movable in Figure 1.

The transfer roller 6 takes a solid line position in Figure 1 (lower position) away from the intermediary transfer member 4 so that it does not disturb the image while the four toner images are being transferred thereonto, that is, while the intermediary transfer member 4 is rotated a plurality of times.

After the toner images are superimposedly transferred onto the intermediary transfer member 4, and the color image formation is completed on the intermediary transfer member 4, the transfer roller 6 is moved to the upper position indicated by the chain line in Figure 1 by unshown cam at timing for transfer of the color image onto the recording material P. Thus, the roller press-contacts the recording member P to the intermediary transfer member 4 at a predetermined. Simultaneously with this, the transfer roller 6 is supplied with a bias voltage so that toner image is transferred from the intermediary transfer member 4 onto the recording material P.

The feeding means 5 for feeding the recording material P, comprises a cassette 5a accommodating a plurality of recording materials P, a pick-up roller 5b, feeding rollers 5c1, retarding rollers 5c2 for preventing double feeding, a pair of feeding rollers 5d, a pair of registration rollers 5e, a pair of discharging rollers 5f, and a feeding guide 5g.

At the time of the image formation, the pick-up roller

5a is rotated in the image forming operation, so that recording material P in the cassette 5a is separated and fed in seriatim. The recording material is fed out of the cassette 5a, and is guided by the feeding guide 5f, and then is fed to the pair of registration rollers 5e via the pair of feeding rollers 5d. In the image forming operation, the registration roller 5e is at rest for stopping and retaining the recording material P, and is rotated to feed the recording material P to the intermediary transfer member 4 at a predetermined sequence to align the recording material P with the intermediary transfer member 4 for the transfer process. Then, the color image is transferred by the transferring means.

The recording material P now having the transferred color image is fed to the fixing means 7 where the toner image is fixed. The fixing means 7 comprises a fixing roller 7a for applying heat to the recording material P, and a pressing roller 7b for press-contacting the recording material P to the fixing roller 7a. These rollers 7a, 7b are hollow rotatable rollers, and have heaters therein. The toner image is fixed on the recording material P while the recording material P is being fed there-through while being pressed and heated.

The recording material P on which the toner image is fixed, is discharged to the discharging portion 8 by the discharging rollers 5f (feeding means).

(Developing Cartridge (Developing Device))

The description will be made as to the developing cartridge for developing the latent image formed on the photosensitive drum 1.

The image forming apparatus has four developing cartridges D (Dy, Dm, Dc, Db) for development in four colors (yellow, magenta, cyan and black) to form a full-color image. The developing cartridges D, as shown in Figures 1 and 2, are demountably mounted on a rotary unit 11 which is rotatable about a shaft 10. In the image formation operation, each developing cartridge D is revolved while being supported on the rotary unit 11, about the shaft 10. A developing cartridge D accommodating predetermined color toner is stopped at a development position faced to the photosensitive drum 1. The developing roller which will be described hereinafter is positioned with small clearance relative to the photosensitive drum 1 (approx. 300 μ m), and then the toner is supplied to the electrostatic latent image on the photosensitive drum 1 to develop the latent image.

During color image formation, the rotary unit 11 is rotated for each rotation of the intermediary transfer member 4 to permit developing operations of the yellow developing cartridge Dy accommodating the yellow color toner, the magenta developing cartridge Dm accommodating the magenta color toner, cyan developing cartridge Dc accommodating the cyan color toner, and the black developing cartridge Db accommodating the black color toner, in this order.

Figure 3 shows a developing cartridge D (yellow de-

veloping cartridge Dy, for example) placed at the development position faced to the photosensitive drum 1. The developing cartridge D comprises a developing roller 12 as a toner carrying member for supplying the toner to the photosensitive drum 1, and a toner accommodating portion 13a for accommodating the toner to be supplied to the developing roller 12. It further comprises a frame 13 for supporting the developing roller 12, and a shutter 14 for an opening provided in the frame 13 to expose the developing roller 12. Furthermore, it comprises a toner feeding member 15 in the toner accommodating portion 13a. A fresh developing cartridge is provided with a toner seal 30 for preventing leakage of the toner accommodated in the toner accommodating portion 13a. A user pulls out the toner seal 30 prior to the mounting of the fresh developing cartridge to the main assembly of the apparatus to open the toner accommodating portion 13a. By this, the toner in the toner accommodating portion 13a is permitted to be supplied to the developing roller 12.

The toner feeding member 15 is rotated by driving force from the main assembly of the apparatus to feed the toner from the accommodating portion 13a to the developing roller 12. The developing roller 12 is a rotatable aluminum roller, and a development blade 16 is press-contacted to the peripheral surface of the developing roller 12. By this, when the developing roller 12 is rotated in the counterclockwise direction in Figure 3, the toner is applied on the peripheral surface as a thin layer, and the toner is supplied with electric charge (triboelectric charge).

The developing roller 12 faced to the photosensitive drum 1 having a latent image, is supplied with a developing bias, so that toner image is formed on the photosensitive drum 1 in accordance with the latent image.

The above-described structure and the developing process are the same in the yellow developing cartridge Dy, the magenta developing cartridge Dm, the cyan developing cartridge Dc and the black developing cartridge Db. The developing roller 12 of each developing cartridge D is connected with the driving source and high voltage generating source for each color development provided in the main assembly of the image forming apparatus when the developing cartridge D is moved to development position, so that developing bias voltage for each developing cartridge D is sequentially applied thereto, and the driving force is transmitted to rotate the developing roller 12 or the like.

The description will be made as to the structure for mounting the developing cartridge D to the main assembly 30 of the image formation device. As shown in Figures 1 to 4, at a predetermined position of the main assembly 30 of the image forming apparatus, an insertion opening 17 having a width not less than the longitudinal direction length of the developing cartridge D, is formed, and a cover 18 is openable mounted in the insertion opening 17. The insertion opening 17 is normally closed by a cover 18.

The main assembly of the apparatus 30 is provided with a developing device exchange switch (unshown). When the developing cartridge D is exchanged after the toner therein is consumed the user actuates the switch. Then, the rotary unit 11 rotates to bring the developing cartridge to be replaced to the position of the insertion opening 17.

When the user opens the cover 18, guides 19 constituting the mounting means for the developing cartridge D are provided at four positions of the rotary unit 11 in the main assembly 30 of the image forming apparatus. On the other hand, the shutter 14 of the developing cartridge D is provided with guide portions 20 as shown in Figures 5 to 10. By inserting the cartridge so that guide portion 20 is guided along the guide 19, the developing cartridge D is inserted into the main assembly 30 of the image forming apparatus. The guide 19 and the guide portion 20 are extended in the longitudinal direction (the direction of the rotation axial direction of) of the developing cartridge D at both sides (only one side is shown in Figures 4 and 5).

After the developing cartridge D is inserted into the main assembly of the apparatus in a direction crossing with the longitudinal direction of the developing roller 12 in this manner, the user rotates the developing cartridge D. The shutter 14 is opened and the developing roller 12 is faced to the photosensitive drum 1 exposed through the frame 13, so that developing operation is enabled.

In this example, the rotary unit 11 as the mounting member carries the black developing cartridge Db for developing the latent image using the black color toner, the yellow developing cartridge Dy for development the latent image using yellow color toner, the magenta developing cartridge Dm for developing the latent image using the magenta color toner, and the cyan developing cartridge Dc for developing the latent image using the cyan color toner.

The structures of the guide 19 and the shutter 14 will be described.

As shown in Figure 6, the frame 13 of the developing cartridge D is provided with an opening 13b extending in the longitudinal direction, and the developing roller 12 is mounted on the frame 13 so as to be exposed through the opening 13b. Substantially at a central portion of each longitudinal end side of the frame 13, a projected portion 13c integral with the frame 13 is formed. The projected portion 13c functions as a guide when the developing cartridge D is inserted into the main assembly 30 of the image forming apparatus and as a center of rotation for the developing cartridge D. At least one of the projected portions 13c is cylindrical.

In both side walls of the shutter 14, round holes 14a are formed, and by engaging the projected portion 13c with the round hole 14a, the shutter 14 is rotatably mounted on the frame 13. As shown in Figure 5, when the shutter 14 is closed, the opening 13 is closed so that developing roller 12 is covered by the shutter 14. When

the developing cartridge D is out of the main assembly of the apparatus 30, the shutter 14 is closed, so that developing roller 12 is protected from deposition of foreign matters such as dust, and the roller 12 or the like is protected from damage.

Adjacent to the projected portion 13c of the frame 13, there is provided a locking member 21 for locking the shutter 14 at the closed state. The locking member 21 has an engaging portion 21b in an arm portion 21a as a supporting portion having an elastic. On the other hand, a shutter engagement recess 14b as an engaging portion is provided at a predetermined position of the shutter side wall.

By this, as shown in Figure 5, when the shutter 14 is in the closed position, the engaging portion 21b is engaged with the engagement recess 14b so that shutter 14 is locked in the closed state, thus preventing unintended opening thereof.

When the developing cartridge D is mounted on the main assembly 30 of the image forming apparatus, the locking is automatically released to permit the opening of the shutter 14. This will be described in more detail.

As shown in Figures 4 - 7, the guide 19 provided on the inner wall of the rotary unit 11, comprises two guiding member inserting portions 19a which are substantially parallel with each other, and a projection inserting portion 19b comprising a linear rib 19b1 and an arcuate rib 19b2. When the developing cartridge D is inserted into the main assembly of the apparatus, the user causes the guide portion 20 of the shutter 14 to be guided by the guide inserting portion 19a, and inserts the developing cartridge D.

When the developing cartridge D is inserted, the projections 13c of the developing cartridge D are brought to the linear portions of the projection inserting portions 19b, as shown in Figure 8. The projected portion 13c has cutting portions 13c1 which are provided by linearly cutting the cylindrical 1 portion in a direction parallel with the linear rib 19b1. The two linear ribs 19b1 engageable therewith, each have a width for permitting movement of the cutting portion 13c1 only in the direction parallel with the cutting portions 13c1. Therefore, when the developing device D is inserted into the main assembly of the apparatus 30, it is maintained at a predetermined angle (orientation) by the cutting portions 13c1 and the linear ribs 19b1.

When the projections 13c are inserted to the arcuate rib 19b2, as shown in Figure 9, a leading end of one of the linear ribs 19b1 is abutted to the arm portion 21a which locks the shutter 14 to raise it upwardly as shown in Figure 9. By this, the arm portion 21a is elastically deformed so that engaging portion 21b is releasable from the engagement recess 14b, and therefore, the locking of the shutter 14 is released (namely, in this embodiment, the linear rib 19b1 is a releasing means for the locking member 21). With this state, the shutter 14 is in a rotatable state relative to the development cartridge frame 13. The arcuate rib 19b2 has a radius for

permitting rotation of the cylindrical projected portion 13c, and the developing cartridge D is in a rotatable state about the cylindrical projected portion 13c.

At both longitudinal ends of the developing cartridge frame 13, projections 13d which are semi-spherical engaging portions are provided as shown in Figure 9, and correspondingly, the shutter 14 has holes 14c which are to be engaged with the projections 13d. Therefore, when the shutter 14 is closed, the projections 13d are engaged with the holes 14c. So, even if the locking by the locking member 21 of the shutter 14 is released, the developing cartridge frame 13 is prevented from rotating to an unstable position relative to the shutter 14.

Subsequently, as shown in Figure 10, the user presses the grip portion 13e of the frame 13. At this time, the cylindrical projected portion 13c of the frame 13 is rotatable in the arcuate rib 19b2 although the shutter 14 is not, because the guide portion 20 is sandwiched by the guide portion inserting portion 19a. Therefore, the semi-spherical projection 13d rotates to the predetermined position beyond the hole 14c of the shutter 14 (x direction in Figure 10). Since the shutter 14 is provided with the insertion guide portion 20, the frame 13 is easily rotated while the shutter 14 is in the fixed state. When it is rotated to a predetermined position, the frame 13 is positioning by a positioning means (unshown), so that developing cartridge D is mounted in place.

By this, the shutter 14 is open to expose and face the developing roller 12 to the photosensitive drum 1. During this mounting operation, the user can feel the rotation start position for the developing cartridge D on the basis of the click feeling provided by the removal of the semi-spherical projection 13d from the hole 14c the shutter 14.

The diameter of the arcuate portion of the projected portion 13c is larger than the distance between the cutting portions 13c1, and therefore, the projected portion 13c is not disengaged from the linear rib 19b1 when the projected portion 13c is rotated at the position of the arcuate rib 19b2.

On the other hand, when the developing cartridge D is removed from the main assembly 30 of the image forming apparatus, The user rotates the frame 13 in the direction opposite from the foregoing, the cutting portions 13c1 become parallel with the linear rib 19b1, and the shutter 14 is closed. The user can feel the rotation completion position of the developing cartridge D on the basis of the click feeling upon the engagement of the semi-spherical projection 13d into the hole 14c. When the developing cartridge D is pulled out of the main assembly of the apparatus 30, the situation is as shown in Figure 8, so that arm portion 21a of the locking member 21 elastically restores to engage the locking portion 21b into the engagement recess 14b. By this, the shutter 14 is automatically locked.

By the provision of the shutter 14 in the developing cartridge D, the developing roller 12 is prevention from contamination by the dust or the like. Since the shutter

14 is provided with a locking mechanism, the shutter 14 is prevented from inadvertent opening.

When the developing device is inserted into the main assembly 30 of image forming apparatus, the shutter 14 maintains its closed state, and therefore, the developing roller 12 is not damaged during insertion. In addition, the user is not required to remove the developing roller protection member by his hands before insertion of the developing cartridge as in conventional system.

Furthermore, the shutter locking is automatically released when the developing cartridge is mounted to the main assembly 30 of the image forming apparatus, and only by rotation thereof after the insertion, the shutter 14 is released, and the developing roller 12 is faced to the photosensitive drum 1, thus completing the mounting operation. Thus, the mounting operativity is improved.

The description will be made as to a drive transmission structure from the main assembly of the apparatus to the developing cartridge D.

As shown in as shown in Figures 11 and 12, a driving force receptor 22 for receiving driving force from the main assembly of the apparatus 30 to rotate the developing roller 12, is provided in one of the cylindrical projected portions 13c at one of the frame ends. The gear 23a is meshed with a roller gear 23b mounted on the rotation shaft of the developing roller 12. When the driving force is transmitted to the receptor 22, the developing roller 12 rotates. The gear 23a is meshed also with the gear 23b mounted on the rotation shaft of the toner feeding member 15 through a gear 23c to transmit the rotating force to the toner feeding member 15.

The end of the driving force receptor 22 is in the form of a rib, which constitutes a coupling connectable with a drive transmission member of the main assembly of the apparatus.

On the other hand, the rotary unit 11 in the main assembly 30 of the image forming apparatus, is provided with a drive transmission member 24 for transmitting the driving force from a motor N, on the shaft faced to the driving force receptor 22 when the developing cartridge D is mounted in place. The transmitting mechanism for transmitting the driving force to the drive transmission member 24 from the motor M, is schematically shown by chain lines. The drive transmission member 24, as shown in Figure 11, is mounted for movement toward the shaft of the driving force receptor portion 22, and the end thereof is formed into a coupling engageable with the rib of the driving force receptor. The coupling has any shape by which when the drive transmission member 24 is moved to the receptor 22, they are engaged, and when one rotates the other rotates. In this example, the receptor 22 has a plurality of recesses 22a, and the drive transmission member 24 is provided with a plurality of projections 24a, correspondingly. By rotation of the drive transmission member 24 while the meshing engagement between the recess 22a and the projection 24a is maintained, the driving force receptor

portion 22 is rotated.

When the developing cartridge D is moved by rotation of the rotary unit 11 in the image formation, The drive transmission member 24 is moved toward the receptor 22 by a moving mechanism (unshown), and is engaged therewith to permit transmission of driving force to the developing roller 12 or the like. By this structures, even if the stop position of the developing cartridge D relative to the photosensitive drum 1 is more or less deviated, or even if the generating lines of the photosensitive drum 1 and the rotary unit 11, are more or less deviated, The driving force transmission to the developing cartridge D is properly transmitted from the same position, and only the driving torque is transmitted, so that influence of the meshing off-set between gears due to pitch non-uniformity or the like can be reduced.

(Second Embodiment)

Referring to Figures 13 and 14, the description will be made as to a structure for stabilizing the pressure of the developing roller 12 to the photosensitive drum 1, according to a second embodiment of the present invention. The same reference numerals as in Embodiment 1 are assigned to the elements having the corresponding functions, and detailed descriptions thereof are omitted for simplicity.

As described in the first embodiment, the developing cartridge D receives the rotating force at the driving force receptor from the drive transmission member 24 of the main assembly 30 of the image forming apparatus at the development position.

As shown in Figure 13, a line X1 is defined as a line connecting a rotation center of the developing cartridge D about the projected portion 13c and the center of rotation of the photosensitive drum 1, and a line X2 is defined as a line connecting the rotation center of the projected portion 13c and the center of rotation of the developing roller 12. When the developing cartridge D is at the development position, The line X2 is located upstream of the line X1 with respect to the driving rotational direction R toward the driving force receptor 22, as seen from the rotation center of the projected portion 13c.

By this structure, the developing roller 12 receives normally the force to bite into the photosensitive drum 1, so that developing roller 12 is stably urged toward the photosensitive drum 1 normally. This is advantageous in the so-called contact development, but it particularly advantageous in the non-contact development since the gap is stabilized.

As shown in Figure 14, the consideration will be made as to the case where an urging means is provided to fix the developing cartridge while urging it toward the photosensitive drum 1 when the developing cartridge is at the development position, When M is a direction of the moment produced in the developing cartridge D by the urging direction P of the urging means; Designated by X1 is a line connecting the center of rotation of the

developing cartridge D provided by the projected portion 13c and the center of rotation of the photosensitive drum 1; Designated by X2 is a line connecting the rotation center of the projected portion 13c and the center of rotation of the developing roller 12; then the line X2 is located upstream of the line X1 with respect to the moment direction M as seen from the rotation center of the projected portion 13c. The same effects are provided with this structure, too. The urging means urges the rear surface portion adjacent the toner accommodating portion 130 at each of the longitudinal ends of the developing cartridge D.

(Third Embodiment)

Referring to Figures 15 to 24, another embodiment of the developing cartridge D will be described. In this embodiment, the developing cartridge D is demountably mountable relative to the full-color laser beam printer shown in Figure 1.

Also, the developing cartridge D comprises a developing roller 12, development blade 16 and toner accommodating portion 63a in the cartridge frame 63.

When the user opens the cover 18, guides 59 constituting mounting means for the developing cartridge D are provided at four positions 4 of the rotary unit 11 in the main assembly 30 of the image forming apparatus. On the other hand, the shutter 64 of the developing cartridge D is provided with a guide portion 70, as shown in Figures 15, 17 and Figure 18. By inserting the cartridge so that guide portion 70 is guided along the guide 19, the developing cartridge D is inserted into the main assembly 30 of the image forming apparatus. The guide portion 70 is provided only on one side (in the longitudinal direction or the rotation axial direction of the developing roller 12) of the developing cartridge D. Therefore, the guide 59 is also provided only on one of the wall surfaces 11a of the rotary unit 11.

The developing cartridge D is inserted to the rotary unit 11 in a direction crossing with the longitudinal direction of the developing roller 12 with the developing roller 12 being at a leading side, while the user grips the grip 63e.

After the developing cartridge D is inserted to the main assembly of the apparatus 30, the user rotates the developing cartridge D, by which the shutter 64 is opened to permit the developing roller 12 to be exposed and faced through the frame 63 to the photosensitive drum 1, thus enabling the developing operation.

The developing cartridge D mounted to the mounting position of the rotary unit 11 is urged in the longitudinal direction by a spherical urging member 26b positioned at the arcuate engaging portion 26a of the guide 26 provided on the other wall surface 11b of the rotary unit 11 (namely, urged to the side having the driving force receptor 22). The urging member 26b is urged elastically by a spring (unshown). The developing cartridge D is urged toward the driving side. Therefore, the

developing cartridge D is mounted to the rotary unit 11 (main assembly of the apparatus), using as a reference the side having the driving force receptor member 22 in the longitudinal direction of the developing roller 12.

The developing cartridge D will be described in more detail, referring to Figure 15, 17, (a), (b), and Figure 18. (a) and (b) Figure 16 is a perspective view of the developing cartridge D wherein shutter 64 or the like is omitted. Figure 17, (a), (b), is both side views of the developing cartridge D when the shutter 64 is closed, and Figure 18 (a) (b) is both side views of the developing cartridge when the shutter 64 is opened.

As shown in Figure 15 the frame 63 of the developing cartridge D is provided with an opening 63b extended in the longitudinal direction and the developing roller 12 is mounted on the frame 63 so as to be exposed through the opening 63b. Substantially at a central portion of one longitudinal direction end side 63h of the frame 63, a projected portion 63c integral with the frame 13 is formed. The projected portion 63c functions as a guide when the developing cartridge D is inserted into the main assembly 30 of the image forming apparatus and as a center of rotation for the developing cartridge D. The projected portions 63c is cylindrical.

At substantially the central portion of the other side of the frame 63, a projected portion 63g is demountably mounted on the frame 63 (frame 63 shows the demounted state). The projected portion 63g is mounted to the frame 63 by inserting the inserting portion 63g1 into a hole (unshown) formed in the side 63i. The end of the inserting portion 63g1 is provided with a claw configuration portion (unshown), and by engaging the claw portion with the frame 63, projected portion 63g is mounted on the frame 63. When the developing cartridge D is mounted to the mounting position of the rotary unit 11, the end surface 63g2 of the projected portion 63g is urged to the member 26b. Therefore, the developing cartridges D urged toward the side 63h (in the direction indicated by the arrow Q). The developing cartridge D is mounted to the rotary unit 11 of the main assembly of the apparatus 30, using, as a reference, the side 63h of the driving force receptor member 22.

Both of the longitudinal ends of the developing roller 12 are provided with spacer rollers 12a, 12b, respectively. Therefore, at the development position, the spacer rollers 12a, 12b are urged to the peripheral surface of the photosensitive drum 1 by the urging force of the urging means 25, similarly to the foregoing, so that predetermined gap is maintained between the developing roller 12 and the photosensitive drum 1.

The developing blade 16 is of rubber, and is mounted to the frame 63 by mounting a plate 16a to the frame with screws 16b.

A locking member 71 is mounted to one side of the developing cartridge D (in Figure 16, it is omitted). The locking member 71 is mounted on a cartridge frame portion 63h at one longitudinal end portion of the developing roller 12 as the developing means. It comprises a lock-

ing engaging portion 71b engageable with the shutter engaging portion 64b provided in the shutter portion 64, a supporting portion 71a for supporting the locking engaging portion 71b, a mounting portion 71c mounted to the cartridge frame portion 63h. Designated by 63j is a hole into which the mounting portion is inserted. The locking member 71 is an integrally-molded product of plastic resin material, and locks the shutter at the closing position by engagement between the locking engaging portion 71b and the shutter engaging portion 64b. In the process of mounting the developing cartridge D to the mounting position of the main assembly of the apparatus 30, a part of the locking member 71 is contacted to a fixing portion provided in the main assembly of the apparatus 30, by which The supporting portion 71a is elastically deformed, so that locking engaging portion 71b is disengaged from the shutter engaging portion 64b to release the locking of the shutter 64.

A projection 63d as a semi-spherical engaging portion is provided only on one longitudinal end of the developing cartridge frame 63, as shown in Figure 18. Correspondingly, the shutter 64 is provided with an engaging portion in the form of a hole 64c engageable with the projection 63d. Therefore, when the shutter 64 is in the closing position, the projection 63d is engaged in hole 64c. So, even if the locking by the locking member 21 of the shutter 14 is released, the developing cartridge frame 13 is prevented from rotating to an unstable position relative to the shutter 14.

One and the other ends of the cartridge frame 63 are provided with an orientation determination boss 63m and a spring receptor portion 63k in the form of projections.

As shown in Figure 17, (a), designated by 73 is a grip for pulling a toner seal out, and it is used when it is to be removed.

The shutter 64 will be described.

Both side walls 64e, 64f of the shutter 64 are provided with round holes 640a, which are engaged with the projected portion 63c, s 63g, by which the shutter 64 is rotatably mounted to the frame 63. As shown in Figure 17, when the shutter 64 is closed, the opening 63b is closed, and the developing roller 12 is covered by the shutter 64. When the developing cartridge D is out of the main assembly of the apparatus 30, the shutter 64 is closed, so that developing roller 12 is protected from deposition of foreign matters such as dust, and the roller 12 or the like is protected from damage. In addition, foreign matter does not enter the developing cartridge D. As shown in Figure 17, when the shutter 64 is in the closing position by the locking portion 71, the shutter 64 is locked at the closing position by the locking of the engaging portion 71b and the engagement recess 64b, so that it is prevented from unintentional opening.

When the developing cartridge D is mounted on the main assembly 30 of the image forming apparatus, the locking is automatically released to permit the opening of the shutter 64.

Referring to Figure 19 - Figure 24, the description will be made as to a process of mounting the developing cartridge D to the main assembly of the apparatus 30, and a process of positioning the main assembly of the apparatus 30.

As shown in Figure 19, a guide 59 as a supporting member provided in one of the inner walls 11a of the rotary unit 11, comprises a guide inserting portion 59b having an inclined portion 59a inclined and open upwardly, a projected portion inserting portion 59d having substantially parallel linear ribs 59c, an engaging portion 59f as a supporting member having an arcuate rib 59e, and guide portion inserting portion 59h having substantially parallel DC ribs 59g continuing to the engaging portion 59f.

When the developing cartridge D is inserted to the main assembly of the apparatus 30, the user inserts the developing cartridge D while guiding the guide portion 70 and projected portion 63c of the shutter 64 along the guide inserting portion 59a (Figure 20).

When the developing cartridge D is inserted, as shown in Figure 21, the projected portion 63c at one end of the developing cartridge D enters the linear portion of the projected portion inserting portion 59d. The projected portion 63c is provided with a cutting portion 63c1 which is provided by linearly cutting a cylinder at an angle parallel the linear rib 59c. The two linear ribs 59c which are engageable therewith has a width which permits only the parallel translational motion of the cutting portion 63c1 (direction W1 in Figure 19). Therefore, when the developing cartridge D is inserted while the cutting portion 63c1 is engaged with the linear rib 59c, the developing cartridge D maintains a predetermined angle (orientation).

As shown in Figure 22, when the projected portion 63c is inserted to the arcuate rib 59e, An end of one of the two inclined portions 59a, is abutted to an arm portion 71a locking the shutter 64 and raises it, as shown in Figure 22. By this, the arm portion 71a elastically deforms so that engaging portion 71b is disengaged from the engagement recess 64b to release the locking of shutter 64 (in this embodiment, the inclined portion 59a also functions to release the locking member 21). Thus, the shutter 64 becomes rotatable relative to the developing cartridge frame 63. The arcuate rib 59e has a radius for permitting rotation of the cylindrical projected portion 63c, and the developing cartridge D is in a rotatable state about the cylindrical projected portion 63c.

On the other hand, the projected portion 63g at the other side 63i of the developing cartridge D, is guided by the inclined portion 26c of the guide 26 and enters the guide inserting portion 26d. When the developing cartridge D is inserted further, the cutting portion 63g3 is engaged with the linear rib 26, and the developing cartridge D is inserted, maintaining the predetermined angle (orientation), similarly to the case of the projected portion 63c. It is inserted until the projected portion 63g reaches the arcuate rib (engaging portion) 26a. The ar-

cuate rib 26a has a radius for permitting rotation of the projected portion 63g. Therefore, the projected portion 63c of one longitudinal end of the frame 63 is supported by the arcuate rib 59c of the guide 59, and the projected portion 63g at the other end is supported by the arcuate rib 26a of the guide 26, and the developing cartridge D is supported on the rotary unit 11 for rotation about the both projected portions 63c and 63g.

The user pushes by hand the grip portion 63e of the frame 63 in the state shown in Figure 22. The shutter 64 is fixed since the guide portion 70 is sandwiched by the guide portion inserting portion 59h, but the frame 63 is rotatable since the cylindrical projected portion 63c is rotatable in the arcuate rib 59e. Since the projected portion 63g is rotatable at the arcuate rib 26a, the semi-spherical projection 63d rotates beyond the hole 64c of the shutter 64 to a predetermined position (in the direction of an arrow X in Figure 22). As described above in the foregoing, in this example, the shutter 64 is provided with an insertion guide portion 70, and therefore, the frame 63 is easily rotated while the shutter 64 is stationary. When it is rotated to the predetermined position, the frame 63 is positioned by positioning means which will be described hereinafter, and the developing cartridge D is mounted in place.

When the developing cartridge D is rotated in the direction indicated by the arrow X in the state shown in Figure 22, the orientation determination bosses 63m provided on the ends 63h, i of the developing device frame 63 lowers translatable slide members 10a provided on the opposite ends of the center shaft 10 of the rotary unit and urged by springs 10b. The slide portion 10a is slidable by engagement between the elongated hole 10a1 and the shaft 10c. When the frame 63 is further rotated, as shown in Figure 24, the spring receptor portion 63k provided on the opposite lateral ends of the frame 63, are pressed by the spring 11a provided at the end portions of the rotary unit. By this, the frame 63 is urged in the direction of rotation in the direction of arrow Y (Figure 24). However, since the orientation determination bosses 63m abut the center shaft 10 of the rotary unit 11, the orientation of the frame 63 is stabilized at the mounting position shown in Figure 24.

Thus, the developing cartridge D is mounted at a predetermined position of the rotary unit 11.

Designated by 11j is a guide portion for guiding the boss 63m.

By this, the shutter 64 is opened relative to the frame 63 to permit the developing roller 12 is exposed and faced to the photosensitive drum 1. During this mounting operation, the user can feel the rotation start position for the developing cartridge D on the basis of the click feeling provided by the removal of the semi-spherical projection 63d from the hole 64c the shutter 64.

The diameter of the arcuate portion of the projected portion 63c is larger than the distance between the cutting portions 63c1, and therefore, the projected portion

63c is not disengaged from the linear rib 59c when the projected portion 63c is rotated at the position of the arcuate rib 59c.

On the other hand, when the developing cartridge D is taken out of the main assembly 30 of the image forming apparatus, the user rotates the frame 63 in the opposite direction, by which the cutting portion 63cl is brought into parallel with the linear rib 59c, and the shutter 64 is closed. The user can feel the rotation completion position of the developing cartridge D on the basis of the click feeling upon the engagement of the semi-spherical projection 63d into the hole 64c. When the developing cartridge D is taken out of the main assembly of the apparatus, the arm portion 71a of the locking member 71 elastically restores, and the engaging portion 71b enters the engagement recess 64b, as shown in Figure 21. By this, the shutter 64 is automatically locked.

Since the developing cartridge D is provided with a shutter 64, the developing roller 12 is protected from deposition of foreign matter such as dust, and since the shutter 64 is provided with the locking mechanism, the shutter 64 is prevented from unintentionally opened.

When the developing device is inserted into the main assembly 30 of image forming apparatus, the shutter 64 maintains its closed state, and therefore, the developing roller 12 is not damaged during insertion. Additionally, it is not necessary for the user to remove a developing roller protection member or the like before insertion of the developing device.

Furthermore, the shutter locking is automatically released when the developing cartridge is mounted to the main assembly 30 of the image forming apparatus, and only by rotation thereof after the insertion, the shutter 64 is released, and the developing roller 12 is faced to the photosensitive drum 1, thus completing the mounting operation. Thus, the mounting operativity is improved.

The description will be made as to positioning of the developing cartridge D.

Referring to Figure 25, arrangements of the spring receptor portion 63k (63k1, 63k2) and the orientation determination boss 63m, will be described.

One longitudinal end portion 63h of the developing roller 12 will be described, and the same applies to the other end portion 63i.

In this example, the spring receptor portion 63k is disposed within a range of approx. 100 - 130 degrees from a line 11 connecting a center of rotation M1 of the developing roller 12 and the center of rotation M2 of the driving force receptor portion 22 as seen in the longitudinal direction of the developing roller 12.

More particularly, in this example, the spring receptor portion 63k1 (63k2) is disposed at such a position that angle formed between the line 11 connecting the center of rotation M1 of the developing roller 12 and the center of rotation M2 of the driving force receptor member 22, and the line 12 connecting the spring receptor

surface 63k3 and the center of rotation M1, is approx. 100 - 130 degrees. In this example, the angle is approx. 115 degrees.

The boss 63m (63m1, 63m2) is disposed within a range of approx. 130 - 150 degrees from the line 11 across the line 11 from the spring receptor portion 63k.

More particularly, in this example, the angle formed between the line 11 and a line 13 connecting the center of the boss 63m and the center of rotation M1, is approx. 130 - 150 degrees. In this example, the angle is approx. 140 degrees.

By disposing the spring receptor portion 63k (63k1, 63k2) and the boss 63m (63m1, 63m2), the spring receptor portion 63k can properly receive the elastic force of the spring 11a provided in the main assembly of the apparatus 30. In addition, the boss 63m properly abuts the shaft 10. Therefore, the developing cartridge D is accurately positioned to the mounting position.

The boss 63m (63m1, 63m2) is projected outwardly from the side surface 63h, i of the frame 62 by approx. 2 mm - 15 mm. In this example, the boss 63m is projected by approx. 4 mm.

The spring receptor portion 63k (63k1, 63k2) is projected outwardly from the side surface 63h, i by approx. 2 mm - 20 mm. In this example, the spring receptor portion 63k1 is projected by approx. 10 mm, and 63k2 is projected by approx. 6 mm. Therefore, a projection length is larger in the spring receptor portion 63k1 provided at a driving force receiving side.

The features of the shutter of the developing cartridge D are summarized as follows.

The developing cartridge for developing a latent image formed on the photosensitive member, wherein said developing cartridge is detachably mountable to a main assembly of an electrophotographic image forming apparatus, and wherein the main assembly includes a main assembly guide for guiding said developing cartridge toward a mounting position in the main assembly, and includes a fixed portion, said developing cartridge comprises: a cartridge frame of plastic resin material; a developing roller 12 for developing, with toner, the latent image formed on the photosensitive member 1 of the main assembly of the apparatus, when mounted to the main assembly of the electrophotographic image forming apparatus, wherein said developing roller carries on its peripheral surface an amount of toner regulated by a development blade 16; a driving force receptor member 22 for receiving, from the main assembly of said device, driving force for rotating said developing roller when said cartridge is mounted to the main assembly, said driving force receptor means being provided exposed adjacent one end of said cartridge frame portion 63h in a longitudinal direction of said developing roller; a toner accommodating portion 63a for accommodating the toner; a shutter 64 of plastic resin material which is movable between a closing position for covering a portion of said developing roller exposed from said cartridge frame portion 63 and an opening position for ex-

posing said developing roller; a cartridge guide 70 for guiding said developing cartridge toward the mounting position by cooperation with said main assembly guide 26, 59 when said developing cartridge is to be mounted to the mounting position, said cartridge guide being provided on said shutter portion 64e which is movable along said cartridge frame portion 63h provided adjacent said one end, wherein said cartridge guide has an elongated shape and is extended toward said driving force receptor member 22; a locking member 71, of plastic resin material, for releasably locking said shutter at said closing position, said locking member 71 including locking engaging portion 71b engageable with a shutter engaging portion 64b provided in said shutter portion, a supporting portion 71a for supporting said locking engaging portion 71b, and a mounting portion 71c mounted on said cartridge frame portion, wherein said locking member is an integrally-molded product of plastic resin material, and said shutter is locked at said closing position by engagement between said locking engaging portion and said shutter engaging portion, wherein in the process of mounting of said developing cartridge to a mounting position of the main assembly of the apparatus, a part of said locking member is contacted to a fixed portion 59a of the main assembly of the apparatus, so that supporting portion 71a is flexed to disengage said locking engaging portion from said shutter engaging portion, thus releasing locking of said shutter; wherein in the process of mounting of said developing cartridge to a mounting position of the main assembly of the apparatus, a part of said locking member is contacted to a fixed portion 59a of the main assembly of the apparatus, so that supporting portion 71a is flexed to disengage said locking engaging portion 71b from said shutter engaging portion 64b, thus releasing locking of said shutter 64, and wherein said shutter is positioned at said opening position by a user rotating said cartridge frame to mount the developing cartridge at the mounting position while said guide is in engagement with a main assembly guide of the main assembly of the apparatus.

Said supporting portion 64e is rotatable about the same axis as that of said driving force receptor member 22.

Said cartridge guide 70 has an elongated shape, and is extended toward said driving force receptor means 22.

Said cartridge D further comprises an urged portion 63g on said cartridge frame portion adjacent said one end, wherein said urged portion is urged by elastic force of a spring member provided in the main assembly of the apparatus, wherein said developing cartridge is urged toward said one end by the elastic force of said spring member.

The features of the structure for the mounting of the developing cartridge D to the main assembly of the apparatus 30 are summarized as follows.

The developing cartridge D for developing a latent image formed on the photosensitive member 1, wherein

said developing cartridge is detachably mountable to a main assembly 30 of an electrophotographic image forming apparatus, said developing cartridge comprises: a cartridge frame 63; developing means (roller 12) for developing, with toner, the latent image formed on the photosensitive member of the main assembly of the apparatus, when mounted to the main assembly of the electrophotographic image forming apparatus; a first projected portion 63c projected from a frame portion 63h of said cartridge adjacent one longitudinal end of said developing means, wherein said first projected portion is supported by a first supporting member 59 provided in the main assembly, when the cartridge is mounted to the main assembly of the electrophotographic image forming apparatus; a second projected portion 63g projected from the frame portion 63i adjacent the other longitudinal end of the developing means, wherein said second projected portion is supported by a second supporting member 26 provided in the main assembly, when the cartridge is mounted to the main assembly of the electrophotographic image forming apparatus; a driving force receptor member 22 for receiving, from the main assembly of the device, driving force for rotating the developing means, when said cartridge is mounted to the main assembly, wherein said driving force receptor member is exposed from said frame portion 63h adjacent said one end; and a guide 70 for guiding said developing cartridge toward a mounting position when said cartridge is mounted to the main assembly.

Said guide 70 is movable along an outside of said frame portion 63g adjacent said one end.

Said guide 70 has an elongated shape, and is rotatable about said driving force receptor member 22. A longitudinal direction of said guide 70 is directed to said driving force receptor member 22. The cartridge further comprises a rotatable member (shutter 64) rotatably mounted on said frame portion 63.

Said guide is provided on said rotatable member.

Said guide 70 is provided on said rotatable member 64.

Said rotatable member 64 includes a shutter 64 for covering a portion of said developing means exposed from said cartridge frame 63.

Said shutter 64 is movable between a closing position for covering said exposed portion and an opening position for exposing said developing means.

Said guide 70 is projected longitudinally outwardly and is provided on said shutter 64.

Said guide 74 is provided on a portion of said shutter 64 which is movable along an outside of said cartridge frame portion 63h adjacent said one end.

Said first projected portion 63c includes two flat surface portions 63c1, opposed to each other, for guiding said developing cartridge toward the mounting position in the main assembly when said cartridge is mounted to said main assembly, and two curved surface portions 63c2, opposed to each other, for engaging with a recess 59f of said first supporting member 59.

Said second projected portion 63g includes two flat surface portions 63g3, opposed to each other, for guiding said developing cartridge toward the mounting position in the main assembly when said cartridge is mounted to said main assembly, and two curved surface portions 63g4, opposed to each other, for engaging with a recess 26a of said second supporting member 26. A distance L1 (Figure 17, (a)) between outside surfaces of said flat surface portion 63c1 of said first projected portion 63c, is larger than a distance L2 (Figure 17, (a)) between outside surfaces of said flat surface portion 63g3 of said second projected portion 63g.

A distance L1 between outer surfaces of said flat surface portions 63c1 of said first projected portion is approx. 13 mm - 15 mm, and a distance L2 between outer surfaces of said flat surface portions 63g3 of said second projected portion 63g is approx. 2 mm - 9 mm. In this embodiment, L1 is approx. 15 mm, and L2 is approx. 9 mm.

A distance L3 (Figure 17, (b)) between remotest outer surface portions of said curved surface portions 63c2 of said first projected portion 63c is approx. 13 mm - 17 mm, and a distance L4 (Figure 17, (a)) between remotest outer surface portions of said curved surface portions 63g4 of said second projected portion 63g is approx. 7 mm - 11 mm. In this embodiment, L3 is approx. 17 mm, and L4 is approx. 11 mm.

Said driving force receptor member 22 is enclosed by said first projected portion 63c. Said driving force receptor member 22 is provided with a recess 22a for engagement with a projection 24a of the main assembly of the apparatus, wherein by engagement between said projection and said recess, driving force is transmitted from the main assembly to said developing means.

Said curved surface portion is of continuous arcuate configuration.

When said developing cartridge D rotates from said mounting position (Figure 24) to a development position (Figures 13 and 14) for developing a latent image formed on the photosensitive member, said developing cartridge rotates about said first projected portion 63c and second projected portion 63g.

Said developing cartridge reaches said mounting position (Figure 24) by approx. 90 - 120 degrees rotation from a mounting-and-demounting position (Figure 22) about said first projected portion 63c and said second projected portion 63g. Said mounting-and-demounting position (Figure 22) is a position where said first projected portion 63c and said second projected portion 63g enters said first supporting member 59 and said second supporting member 26, and where said flat surface portion 63g3 is opposing to engaging portions of said first supporting member and said second supporting member, respectively. In this embodiment, it is rotated through approx. 105 degrees.

Said developing cartridge reaches a developing position by approx. 5 - 10 degrees rotation from said mounting position about the first projected portion 63c

and the second projected portion 63g. Said developing position is a position where spacer rollers 12a of said developing member is urged to said electrophotographic photosensitive member 1. In this embodiment, it is rotated through approx. 7 degrees.

The guide 70 functions to guide the developing cartridge D into the main assembly, and is displaceable relative to the first projection.

The guide 70 has an elongated shape, and rotates through approx. 90 - 120 degrees the first projected portion 63c to mounted the developing cartridge at the mounting position in main assembly of the apparatus.

The cartridge further comprises a driving force receptor member 22 for receiving, from the main assembly of said device, driving force for rotating said developing roller 12 when said developing cartridge is mounted to the main assembly of said device, wherein said driving force receptor member 22 is provided on the same longitudinal end as having said first projected portion 63c, and wherein said guide is provided only of the same side. Thus, the guide 70 is provided only on one side 63h, and therefore, the developing cartridge D can be smoothly mounted.

The mounting position of the developing cartridge is a position where the developing cartridge is correctly positioned in place in the main assembly of the apparatus.

The development position of the developing cartridge is a position where the developing cartridge is positioned for effecting the development operation.

The mounting-and-demounting position of the developing cartridge is a position where the developing cartridge is mounted to or demounted from the supporting member provided in the main assembly of the apparatus. The supporting member is a member for supporting the developing cartridge when the developing cartridge is to be mounted to the mounting position.

The features for the positioning of the developing cartridge D relative to the main assembly of the apparatus are summarized as follows.

The developing cartridge D for developing a latent image formed on the photosensitive member 1, wherein said developing cartridge is detachably mountable to a main assembly 30 of an electrophotographic image forming apparatus, said developing cartridge comprises: a cartridge frame 63; developing roller 12 for developing, with toner, the latent image formed on the photosensitive member 1 of the main assembly of the apparatus, when mounted to the main assembly of the electrophotographic image forming apparatus; a first projected portion 63c outwardly projected from said cartridge frame portion 63h adjacent one longitudinal end of said developing means, wherein said first projected portion is supported by a first supporting member 59 provided in the main assembly 30 of the apparatus when said cartridge is mounted to the main assembly; a second projected portion 63g outwardly projected from said cartridge frame portion adjacent the other longitudinal

nd of said developing means, wherein said second projected portion is supported by a second supporting member 26 provided in the main assembly of the apparatus when said cartridge is mounted to the main assembly 30; a first urging force receptor portion 63kl outwardly projected from said cartridge frame portion 63h adjacent one longitudinal end of said developing means, wherein said first urging force receptor portion receives urging force by a first elastic member 11a provided in the main assembly 30 when said cartridge is mounted to the main assembly, and wherein said first urging force receptor portion is integrally molded with said cartridge frame; a second urging force receptor portion 63k2 outwardly projected from said cartridge frame portion 63i adjacent the other longitudinal end of said developing means, wherein said second urging force receptor portion receives urging force by a second elastic member 11a provided in the main assembly when said cartridge is mounted to the main assembly, and wherein said second urging force receptor portion is integrally molded with said cartridge frame; a first contact portion 63m1 outwardly projected from said cartridge frame portion 63h adjacent one longitudinal end of said developing means, wherein said first contact portion contacts a first fixed portion 10 provided in the main assembly when said cartridge is mounted to the main assembly, wherein said first contact portion is integrally molded with said cartridge frame; a second contact portion 63m2 outwardly projected from said cartridge frame portion 63i adjacent one longitudinal end of said developing means, wherein said second contact portion contacts a second fixed portion 10 provided in the main assembly when said cartridge is mounted to the main assembly, and wherein said second contact portion is integrally molded with said cartridge frame; a driving force receptor member 22 for receiving, from the main assembly 30, driving force for rotating said developing means when said cartridge is mounted to the main assembly, wherein said driving force receptor member is exposed from said cartridge frame portion adjacent one longitudinal end of said developing roller; wherein as seen in a direction substantially perpendicular to the longitudinal direction of said developing means, said first urging force receptor portion and second urging force receptor portion are within a range of approx. 100 - 130 degrees from a line connecting a center of rotation of said developing means and a center of rotation of said driving force receptor member, and wherein said first contact portion and second contact portion are within a range of approx. 130 - 150 degrees.

The first receptor portion 63k and the second one 63k are flat in shape, and receive the urging forces from the first urging member 11a and the second one 11a.

Said first contact portion 63m1 and second contact portion 63m2 are in the form of circular columns, and its peripheral surface portions are contacted to said first fixed portion 10 and second fixed portion 10.

The structures of the cartridge frame, the develop-

ing roller, the driving force receptor member, the toner accommodating portion, the shutter, cartridge guide, the locking member, the fixing portion, the first projected portion, the second projected portion, the first and second urging force receptors, the portion, the second urging force receptor, the portion, the first contact portion, the second contact portion, the first fixing portion, and second fixing portion, are not limited to those described above, but may be modified.

A further embodiment will be described.

Figure 26 is a side view of one end of the developing cartridge D.

In this example, another shape of the projected portion 63c is used.

It is not inevitable to cut a cylindrical portion provided on an end surface of the frame 63 of the developing cartridge D to provide the projected portion 63c. As shown in Figure 25, the linear portion 63c1 may be provided with at least one projection 63c3 so that width is smaller than the rib clearance W1 (Figure 19) of the inlet of the guide 59. The insertion is possible with the structure.

By this, the contact resistance with the rib of the guide 59 can be reduced to make the insertion of the developing cartridge D smoother.

Referring to Figure 27, a further embodiment will be described.

In Figure 27, cylindrical projection 63c provided on a side 63h of the frame 63 of the developing cartridge, has a configuration having a plurality of projections 63c4 contactable to the arcuation of such a diameter D2 as is engageable with the diameter D1 (Figure 19) of the arcuate rib of the guide 59.

By this, the contact resistance with the rib of the guide 59 can be decreased to make smooth the rotation upon mounting of the developing cartridge D to the main assembly of the apparatus 30.

Figure 28 shows a further example wherein the structures of Figures 26 and 27 are used in combination, as will be understood from this Figure.

Referring to Figure 29, another embodiment will be described.

In this embodiment, the shutter 80 is removed from the cartridge frame 63 by a user, or is mounted by the user. The guide 70 is provided in a rotatable member not in the shutter 80. The rotatable member 81 is rotatable about a projection 63c along a side 63h of the cartridge frame. It is locked by the above-described locking member 71. Therefore, the guide 70 has the same function as described in the foregoing, and the developing cartridge D can be mounted to the main assembly 30 in the same manner.

Prior to mounting the developing cartridge D to the main assembly 30, the shutter 80 is removed from the frame 63 by the user. When the cartridge D is demounted from the main assembly 30, the shutter is remounted to the frame by the user, as desired. The shutter is not inevitable, and may not be provided.

The guide 70 may not be provided on the rotatable member 81, but may be mounted directly on the cartridge frame. In this case, the guide is rotatably mounted on the cartridge frame 63.

According to the foregoing embodiments, the projections on longitudinal end surfaces of the developing cartridge frame, are guided when the developing cartridge is mounted to the main assembly of the image forming apparatus, so that developing cartridge can be inserted in a direction perpendicular to the longitudinal direction, and therefore, the insertion stroke can be reduced to improve the insertion operativity.

The driving connection between the developing cartridge and the main assembly, is effected with the coupling configuration, so that decrease of the driving accuracy due to the driving gear pitch nonuniformity, for example, can be prevented.

The foregoing cartridge frame, shutter or the like are of plastic resin material such as polystyrene, ABS resin, polycarbonate, polyethylene, polypropylene, or the like.

The process cartridge is not limited to those described in the foregoing, but may contain as an unit at least one process means such as charging means, cleaning means or the like, and an electrophotographic photosensitive member, wherein cartridge is detachably mountable relative to the main assembly of an electrophotographic image forming apparatus.

According to the present invention, the mounting operativity of the developing cartridge is improved.

Additionally, the developing cartridge can be mounted in the main assembly of the electrophotographic image forming apparatus with high positional accuracy.

Furthermore, since the urging force receptor portion and the contact portion are projected outwardly from the cartridge frame, the configuration of the cartridge frame can be selected with higher latitude.

While the invention has been described with reference to the structures disclosed herein, it is not confined to the details set forth and this application is intended to cover such modifications or changes as may come within the purposes of the improvements or the scope of the following claims.

Claims

1. A developing cartridge for developing a latent image formed on the photosensitive member, wherein said developing cartridge is detachably mountable to a main assembly of an electrophotographic image forming apparatus, said developing cartridge comprising:

a cartridge frame;
developing means for developing, with toner, the latent image formed on the photosensitive member of the main assembly of the apparatus, when mounted to the main assembly of the

electrophotographic image forming apparatus;
a first projected portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first projected portion is supported by a first supporting member provided in the main assembly of the apparatus when said cartridge is mounted to the main assembly;

a second projected portion outwardly projected from said cartridge frame portion adjacent the other longitudinal end of said developing means, wherein said second projected portion is supported by a second supporting member provided in the main assembly of the apparatus when said cartridge is mounted to the main assembly;

a first urging force receptor portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first urging force receptor portion receives urging force by a first elastic member provided in the main assembly when said cartridge is mounted to the main assembly;
a second urging force receptor portion outwardly projected from said cartridge frame portion adjacent the other longitudinal end of said developing means, wherein said second urging force receptor portion receives urging force by a second elastic member provided in the main assembly when said cartridge is mounted to the main assembly;

a first contact portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first contact portion contacts a first fixed portion provided in the main assembly when said cartridge is mounted to the main assembly;
a second contact portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said second contact portion contacts a second fixed portion provided in the main assembly when said cartridge is mounted to the main assembly.

2. A cartridge according to Claim 1, wherein as seen in a direction substantially perpendicular to the longitudinal direction of said developing means, said first urging force receptor portion and second urging force receptor portion are within a range of approx. 100 - 130 degrees from a line connecting a center of rotation of said developing means and a center of rotation of said driving force reception member.
3. A cartridge according to Claim 1 or 2, wherein as seen in a direction substantially perpendicular to the longitudinal direction of said developing means, said first contact portion and second contact portion

are within a range of approx. 130 - 150 degrees from a line connecting a center of rotation of said developing means and a center of rotation of said driving force reception member.

4. A cartridge according to Claim 1, wherein said first urging force receptor portion and second urging force receptor portion are in the form of flat plates, and reception the urging force by said first elastic member and the urging force by said second elastic member. 5 10
5. A cartridge according to Claim 4, wherein said first urging force receptor portion is integrally molded with a first frame member constituting said cartridge frame, and said second urging force receptor portion is integrally molded with a second frame member constituting said cartridge frame. 15
6. A cartridge according to Claim 4 or 5, wherein said first urging force receptor portion and second urging force receptor portion are projected outwardly from said cartridge frame by approx. 2 mm - 15 mm. 20
7. A cartridge according to Claim 1, wherein said first contact portion and second contact portion are in the form of circular columns, and its peripheral surface portions are contacted to said first fixed portion and second fixed portion. 25 30
8. A cartridge according to Claim 7, wherein said first contact portion is integrally molded with said cartridge frame, and said second contact portion is integrally molded with said cartridge frame. 35
9. A cartridge according to Claim 7 or 8, wherein said first contact portion and second contact portion are outwardly projected from said cartridge frame by approx. 2 mm - 20 mm. 40
10. A cartridge according to Claim 1, wherein said first projected portion and said second projected portion have flat surface portions and curved surface portions, and said curved surface portions are rotatably engaged with said first supporting portion and second supporting portion, respectively. 45
11. A developing cartridge for developing a latent image formed on the photosensitive member, wherein said developing cartridge is detachably mountable to a main assembly of an electrophotographic image forming apparatus, said developing cartridge comprising: 50
 - a cartridge frame; 55
 - developing roller for developing, with toner, the latent image formed on the photosensitive member of the main assembly of the apparatus,

when mounted to the main assembly of the electrophotographic image forming apparatus; a first projected portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first projected portion is supported by a first supporting member provided in the main assembly of the apparatus when said cartridge is mounted to the main assembly; a second projected portion outwardly projected from said cartridge frame portion adjacent the other longitudinal end of said developing means, wherein said second projected portion is supported by a second supporting member provided in the main assembly of the apparatus when said cartridge is mounted to the main assembly; a first urging force receptor portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first urging force receptor portion receives urging force by a first elastic member provided in the main assembly when said cartridge is mounted to the main assembly; a second urging force receptor portion outwardly projected from said cartridge frame portion adjacent the other longitudinal end of said developing means, wherein said second urging force receptor portion receives urging force by a second elastic member provided in the main assembly when said cartridge is mounted to the main assembly; a first contact portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first contact portion contacts a first fixed portion provided in the main assembly when said cartridge is mounted to the main assembly; a second contact portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said second contact portion contacts a second fixed portion provided in the main assembly when said cartridge is mounted to the main assembly; a driving force receptor member for receiving, from the main assembly, driving force for rotating said developing means when said cartridge is mounted to the main assembly, wherein said driving force receptor member is exposed from said cartridge frame portion adjacent one longitudinal end of said developing roller, wherein as seen in a direction substantially perpendicular to the longitudinal direction of said developing means, said first urging force receptor portion and second urging force receptor portion are within a range of approx. 100 - 130 degrees from a line connecting a center of ro-

tation of said developing means and a center of rotation of said driving force reception member.

12. A cartridge according to Claim 11, wherein said first urging force receptor portion and second urging force receptor portion are in the form of flat plates, and reception the urging force by said first elastic member and the urging force by said second elastic member. 5
13. A cartridge according to Claim 12, wherein said first urging force receptor portion is integrally molded with a first frame member constituting said cartridge frame, and said second urging force receptor portion is integrally molded with a second frame member constituting said cartridge frame. 10
14. A cartridge according to Claim 12 or 13, wherein said first urging force receptor portion and second urging force receptor portion are projected outwardly from said cartridge frame by approx. 2 mm - 15 mm. 15
15. A cartridge according to Claim 11, wherein said first contact portion and second contact portion are in the form of circular columns, and its peripheral surface portions are contacted to said first fixed portion and second fixed portion. 20
16. A cartridge according to Claim 15, wherein said first contact portion is integrally molded with said cartridge frame, and said second contact portion is integrally molded with said cartridge frame. 25
17. A cartridge according to Claim 15 or 16, wherein said first contact portion and second contact portion are outwardly projected from said cartridge frame by approx. 2 mm - 20 mm. 30
18. A cartridge according to Claim 11, wherein said first projected portion and said second projected portion have flat surface portions and curved surface portions, and said curved surface portions are rotatably engaged with said first supporting portion and second supporting portion, respectively. 35
19. A developing cartridge for developing a latent image formed on the photosensitive member, wherein said developing cartridge is detachably mountable to a main assembly of an electrophotographic image forming apparatus, said developing cartridge comprising: 40
 - a cartridge frame; 45
 - developing roller for developing, with toner, the latent image formed on the photosensitive member of the main assembly of the apparatus, 50

when mounted to the main assembly of the electrophotographic image forming apparatus; a first projected portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first projected portion is supported by a first supporting member provided in the main assembly of the apparatus when said cartridge is mounted to the main assembly; a second projected portion outwardly projected from said cartridge frame portion adjacent the other longitudinal end of said developing means, wherein said second projected portion is supported by a second supporting member provided in the main assembly of the apparatus when said cartridge is mounted to the main assembly; a first urging force receptor portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first urging force receptor portion receives urging force by a first elastic member provided in the main assembly when said cartridge is mounted to the main assembly, and wherein said first urging force receptor portion is integrally molded with said cartridge frame; a second urging force receptor portion outwardly projected from said cartridge frame portion adjacent the other longitudinal end of said developing means, wherein said second urging force receptor portion receives urging force by a second elastic member provided in the main assembly when said cartridge is mounted to the main assembly, and wherein said second urging force receptor portion is integrally molded with said cartridge frame; a first contact portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first contact portion contacts a first fixed portion provided in the main assembly when said cartridge is mounted to the main assembly, wherein said first contact portion is integrally molded with said cartridge frame; a second contact portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said second contact portion contacts a second fixed portion provided in the main assembly when said cartridge is mounted to the main assembly, and wherein said second contact portion is integrally molded with said cartridge frame; a driving force receptor member for receiving, from the main assembly, driving force for rotating said developing means when said cartridge is mounted to the main assembly, wherein said

driving force receptor member is exposed from said cartridge frame portion adjacent one longitudinal end of said developing roller; wherein as seen in a direction substantially perpendicular to the longitudinal direction of said developing means, said first urging force receptor portion and second urging force receptor portion are within a range of approx. 100 - 130 degrees from a line connecting a center of rotation of said developing means and a center of rotation of said driving force reception member, and wherein said first contact portion and second contact portion are within a range of approx. 130 - 150 degrees

20. A cartridge according to Claim 19 wherein said first urging force receptor portion and second urging force receptor portion are in the form of flat plates, and reception the urging force by said first elastic member and the urging force by said second elastic member.
21. A cartridge according to Claim 19 or 20, wherein said first urging force receptor portion and second urging force receptor portion are projected outwardly from said cartridge frame by approx. 2 mm - 15 mm.
22. A cartridge according to Claim 19, wherein said first contact portion and second contact portion are in the form of circular columns, and its peripheral surface portions are contacted to said first fixed portion and second fixed portion.
23. A cartridge according to Claim 19 or 20, wherein said first contact portion and second contact portion are outwardly projected from said cartridge frame by approx. 2 mm - 20 mm.
24. A cartridge according to Claim 19, wherein said first projected portion and said second projected portion have flat surface portions and curved surface portions, and said curved surface portions are rotatably engaged with said first supporting portion and second supporting portion, respectively.
25. An electrophotographic image forming apparatus for forming an image on a recording material, comprising:
 - a. an electrophotographic photosensitive member;
 - b. a first supporting member;
 - c. a second supporting member;
 - d. a first elastic member;
 - e. a second elastic member;
 - f. a first fixed portion;
 - g. a second fixed portion;

h. a cartridge frame;

a mounting member for mounting a developing cartridge;
 said developing cartridge including:
 developing means for developing, with toner, the latent image formed on the photo-sensitive member of the main assembly of the apparatus, when mounted to the main assembly of the electrophotographic image forming apparatus;
 a first projected portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first projected portion is supported by a first supporting member provided in the main assembly of the apparatus when said cartridge is mounted to the main assembly;
 a second projected portion outwardly projected from said cartridge frame portion adjacent the other longitudinal end of said developing means, wherein said second projected portion is supported by a second supporting member provided in the main assembly of the apparatus when said cartridge is mounted to the main assembly;
 a first urging force receptor portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first urging force receptor portion receives urging force by a first elastic member provided in the main assembly when said cartridge is mounted to the main assembly;
 a second urging force receptor portion outwardly projected from said cartridge frame portion adjacent the other longitudinal end of said developing means, wherein said second urging force receptor portion receives urging force by a second elastic member provided in the main assembly when said cartridge is mounted to the main assembly;
 a first contact portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first contact portion contacts a first fixed portion provided in the main assembly when said cartridge is mounted to the main assembly;
 a second contact portion outwardly projected from said cartridge frame portion adjacent on longitudinal end of said developing means, wherein said second contact portion contacts a second fixed portion provided in the main assembly when said cartridge is mounted to the main assembly;

i. a driving force transmission member for transmitting driving force to said developing cartridge mounted to said mounting member.

26. An apparatus according to Claim 25, wherein a black developing cartridge for developing a latent image with black color toner, a yellow developing cartridge for developing a latent image with yellow color toner, magenta developing cartridge for developing a latent image with magenta color toner, and a cyan developing cartridge for developing a latent image with cyan color toner, are mountable to said mounting member.
27. An apparatus according to Claim 25, wherein said electrophotographic photosensitive member is contained in a process cartridge detachably mountable to a main assembly of said image forming apparatus, said process cartridge further containing a charging member for charging said electrophotographic photosensitive member and cleaning member for removing residual toner from said electrophotographic photosensitive member.
28. An apparatus according to Claim 25, wherein said driving force receptor means is provided with a recess, which is engageable with a projection of said driving force transmitting means to receive driving force from said motor.
29. An electrophotographic image forming apparatus for forming an image on a recording material, comprising:
- a. an electrophotographic photosensitive member;
 - b. a first supporting member;
 - c. a second supporting member;
 - e. a first elastic member;
 - f. a second elastic member;
 - g. a first fixed portion;
 - h. a second fixed portion;
 - i. a cartridge frame;
- developing roller for developing, with toner, the latent image formed on the photosensitive member of the main assembly of the apparatus, when mounted to the main assembly of the electrophotographic image forming apparatus;
- a first projected portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first projected portion is supported by a first supporting member provided in the main assembly of the apparatus when said cartridge is mounted to the main assembly;

a second projected portion outwardly projected from said cartridge frame portion adjacent the other longitudinal end of said developing means, wherein said second projected portion is supported by a second supporting member provided in the main assembly of the apparatus when said cartridge is mounted to the main assembly;

a first urging force receptor portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first urging force receptor portion receives urging force by a first elastic member provided in the main assembly when said cartridge is mounted to the main assembly;

a second urging force receptor portion outwardly projected from said cartridge frame portion adjacent the other longitudinal end of said developing means, wherein said second urging force receptor portion receives urging force by a second elastic member provided in the main assembly when said cartridge is mounted to the main assembly;

a first contact portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first contact portion contacts a first fixed portion provided in the main assembly when said cartridge is mounted to the main assembly;

a second contact portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said second contact portion contacts a second fixed portion provided in the main assembly when said cartridge is mounted to the main assembly;

a driving force receptor member for receiving, from the main assembly, driving force for rotating said developing means when said cartridge is mounted to the main assembly, wherein said driving force receptor member is exposed from said cartridge frame portion adjacent one longitudinal end of said developing roller;

wherein as seen in a direction substantially perpendicular to the longitudinal direction of said developing means, said first urging force receptor portion and second urging force receptor portion are within a range of approx. 100 - 130 degrees from a line connecting a center of rotation of said developing means and a center of rotation of said driving force reception member, and wherein said first contact portion and second contact portion are within a range of

approx. 130 - 150 degrees;

j. a driving force transmission member for transmitting driving force to said driving force receptor member of developing cartridge when said cartridge is mounted to said mounting member. 5

30. An apparatus according to Claim 29, wherein a black developing cartridge for developing a latent image with black color toner, a yellow developing cartridge for developing a latent image with yellow color toner, magenta developing cartridge for developing a latent image with magenta color toner, and a cyan developing cartridge for developing a latent image with cyan color toner, are mountable to said mounting member. 10 15

31. An apparatus according to Claim 29, wherein said electrophotographic photosensitive member is contained in a process cartridge detachably mountable to a main assembly of said image forming apparatus, said process cartridge further containing a charging member for charging said electrophotographic photosensitive member and cleaning member for removing residual toner from said electrophotographic photosensitive member. 20 25

32. An apparatus according to Claim 29, wherein said driving force transmission member has a projection, which is engageable with a recess of said driving force receptor member to transmit driving force. 30

33. An electrophotographic image forming apparatus for forming an image on a recording material, comprising: 35

- a. an electrophotographic photosensitive member;
- b. a first supporting member;
- c. a second supporting member; 40
- d. first elastic member;
- e. second elastic member;
- f. first fixed portion;
- g. second fixed portion;
- g. cartridge frame; 45

developing roller for developing, with toner, the latent image formed on the photosensitive member of the main assembly of the apparatus, when mounted to the main assembly of the electrophotographic image forming apparatus; 50

a first projected portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first projected portion is supported by a first supporting member provided in the main assembly of the 55

apparatus when said cartridge is mounted to the main assembly;

a second projected portion outwardly projected from said cartridge frame portion adjacent the other longitudinal end of said developing means, wherein said second projected portion is supported by a second supporting member provided in the main assembly of the apparatus when said cartridge is mounted to the main assembly;

a first urging force receptor portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first urging force receptor portion receives urging force by a first elastic member provided in the main assembly when said cartridge is mounted to the main assembly, and wherein said first urging force receptor portion is integrally molded with said cartridge frame;

a second urging force receptor portion outwardly projected from said cartridge frame portion adjacent the other longitudinal end of said developing means, wherein said second urging force receptor portion receives urging force by a second elastic member provided in the main assembly when said cartridge is mounted to the main assembly, and wherein said second urging force receptor portion is integrally molded with said cartridge frame;

a first contact portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said first contact portion contacts a first fixed portion provided in the main assembly when said cartridge is mounted to the main assembly, wherein said first contact portion is integrally molded with said cartridge frame;

a second contact portion outwardly projected from said cartridge frame portion adjacent one longitudinal end of said developing means, wherein said second contact portion contacts a second fixed portion provided in the main assembly when said cartridge is mounted to the main assembly, and wherein said second contact portion is integrally molded with said cartridge frame; a driving force receptor member for receiving, from the main assembly, driving force for rotating said developing means when said cartridge is mounted to the main assembly, wherein said driving force receptor member is exposed from said cartridge frame portion adjacent one longitudinal end of said developing roller;

wherein as seen in a direction substantially perpendicular to the longitudinal direction of said developing means, said first urging force receptor portion and second urging force receptor portion are within a range of approx. 100 - 130 degrees from a line connecting a center of rotation of said developing means and a center of rotation of said driving force reception member, and wherein said first contact portion and second contact portion are within a range of approx. 130 - 150 degrees;

j. a driving force transmission member for transmitting driving force to said driving force receptor member of developing cartridge when said cartridge is mounted to said mounting member.

34. An apparatus according to Claim 33, wherein a black developing cartridge for developing a latent image with black color toner, a yellow developing cartridge for developing a latent image with yellow color toner, magenta developing cartridge for developing a latent image with magenta color toner, and a cyan developing cartridge for developing a latent image with cyan color toner, are mountable to said mounting member.

35. An apparatus according to Claim 33, wherein said electrophotographic photosensitive member is contained in a process cartridge detachably mountable to a main assembly of said image forming apparatus, said process cartridge further containing a charging member for charging said electrophotographic photosensitive member and cleaning member for removing residual toner from said electrophotographic photosensitive member.

36. An apparatus according to Claim 33, wherein said driving force transmitting member has a projection, which is engageable with a recess of said driving force receptor member to transmit the driving force.

37. Electrophotographic image forming apparatus comprising a developer cartridge, a carrier into which the cartridge is removably mounted, and resilient means for biasing the cartridge for translational movement relative to the carrier to urge a development roller of the cartridge towards its working position.

38. Electrophotographic image forming apparatus comprising a developer cartridge, a carrier into which the cartridge is removably mounted and resilient means for biasing the cartridge for rotational movement relative to the carrier to urge a development roller of the cartridge towards its working position.

39. Electrophotographic image forming apparatus comprising a developer cartridge, a carrier into which the cartridge is removably mounted, first resilient means for biasing the cartridge for translational movement relative to the carrier to urge a development roller of the cartridge towards its working position, and second resilient means for biasing the cartridge for rotational movement relative to the carrier to urge the development roller of the cartridge towards its working position.

40. The apparatus of claim 37, 38 or 39, wherein the apparatus is a multi-colour image forming apparatus and the carrier is cylindrical and has positions spaced apart around its circumference for mounting developer cartridges for respective colours.

41. A developer cartridge for fitting to an electrophotographic image forming apparatus, said cartridge comprising a casing, developer means in the casing, an opening in the casing for enabling the developer means to cooperate with a latent image bearing member of the apparatus with which the cartridge is to be used, and first, second and third axially projecting support means at one end of the casing, the first support means being engageable with the apparatus to provide an axis for rotational movement of the cartridge and the second and third support means being engageable with resilient means of the apparatus for positioning of the cartridge, the second and third support means being radially spaced from the first support means and spaced angularly apart with reference to the first support means.

42. The cartridge of claim 41, wherein the second and third support means are spaced apart along radii which make an obtuse angle with reference to the first support means.

43. Electrophotographic image forming apparatus comprising a main body, support means for supporting a developer cartridge in the main body, and a developer cartridge removably mounted in the support means, the support means being arranged such that the cartridge mounted therein is rotatable between operative and inoperative positions, there being provided latch means which operates through an over-centre position when the cartridge is rotated to its operative position for holding said cartridge in said operative position.

44. Apparatus according to claim 43, wherein first and second resilient means are provided, the first of which is for providing the resilience of said over-centre latch means and the second of which is for opposing the first resilient means and for urging the cartridge towards its operative position.

45. A developer cartridge for an electrophotographic image forming apparatus, comprising a casing, developer means in the casing, a first support member at an end of the cartridge engageable with the apparatus to provide rotatable support for the cartridge, and second and third support members at an end of the cartridge for engagement with resilient means of the apparatus for positioning the cartridge, the cartridge having an opening in which the developing means is exposed for cooperation with a latent image bearing member of the apparatus, the second and third support members and the opening being on opposite sides of the first support member and the second and third support members being spaced from the first support member along radii which are disposed angularly apart. 5 10 15
46. A developer cartridge for an electrophotographic image forming apparatus, comprising a casing, developer means in the casing, a first support member at an end of the cartridge engageable with the apparatus to provide rotatable support for the cartridge, and second and third support members at an end of the cartridge for engagement with resilient means of the apparatus for positioning the cartridge, the cartridge having an opening in which the developing means is exposed for cooperation with a latent image bearing member of the apparatus, the opening and the second and the second and third support members being spaced apart along radii which are angularly distributed with reference to the first support member. 20 25 30
47. The cartridge of claim 46, wherein the second and third support members are disposed along radii which make an obtuse angle with reference to the first support member. 35
48. The cartridge of claim 47, wherein the opening is disposed along a radius which is at a reflex angle with reference to the first support member. 40
